Most aircraft are designed with greater directional stability, and therefore a small disturbance in the rolling direction tends to lead to greater banking. If not counterbalanced by the pilot or electronic control system, the aircraft could enter an ever-increasing diving turn.

Stability and control analysis is an important discipline to consider when designing an aircraft. An appropriate analysis can overcome deficiencies enforced by others disciplines, such as aerodynamics and loads. The efficiency of the control surfaces can also be maximized by a proper analysis.

### AIRCRAFT STABILITY AND CONTROL ANALYSIS

An autopilot is a system used to control the trajectory of an aircraft, marine craft or spacecraft without requiring constant manual control by a human operator. Autopilot does not replace human operators. Instead, autopilot assists the operator's control of the vehicle, allowing the operator to focus on broader aspects of operations. When present, autopilot is often used in conjunction with an autothrottle, a system for controlling the power delivered by the engines. An autopilot system is some

### Autopilot - Wikipedia

Stability is the ability of an aircraft to correct for conditions that act on it, like turbulence or flight control inputs. For aircraft, there are two general types of stability: static and dynamic. Most aircraft are built with stability in mind, but that's not always the case. Some aircraft, like training airplanes, are built to be very stable.

This widely used book has been updated with modern flying quality criteria and aerodynamic data.

### **Airplane Flight Dynamics & Automatic Flight Controls**

- Stability and Control: in which the short- and intermediate-time response of the attitude and velocity of the vehicle is considered. Stability considers the response of the vehicle to perturbations in flight conditions from some dynamic equilibrium, while control considers the response of the vehicle to control inputs.
