The course I took covered Lagrangian and Hamiltonian mechanics and also covered Poisson brackets and the Hamilton-Jacobi formulation. I found the book *Introductory Classical Mechanics* by David Morin to be useful and have many problems with detailed solutions for it. It was especially useful for the Lagrangian part of the course.

However, we will also cover material that is not in Goldstein, in particular in our discussion of fluid dynamics and chaos.

Classical mechanics is a physical theory describing the motion of macroscopic objects, from projectiles to parts of machinery, and astronomical objects, such as spacecraft, planets, stars and galaxies. For objects governed by classical mechanics, if the present state is known, it is possible to predict how it will move in the future (determinism) and how it has moved in the past (reversibility).

Studying physics again, after I got doctoral degree in mathematics, I have had to study Lagrange's equations and Hamiltonian mechanics. Instead of re-reading Simons' book or trying Goldstein's book, I chose J. Taylor's Classical Mechanics for my self-study, because the Amazon.com reviews on Taylor's book were of full praises.

Here Δq is the uncertainty in the position
of the particle (in meters), Δv is the
uncertainty in its speed (in meters per
second), m is its mass in kg, and \hbar is a
constant (planck's constant) divided by
 2π). It is applicable for only
microscopic particles which follow the
quantum mechanics as it is itself the
consequence of quantum mechanics.
